11.1 Sensitivity Functions In the previous chapter, we considered the use of proportional-integral-derivative (PID) feedback as a mechanism for designing a feedback controller for a given process. In this chapter we will expand our approach to include a richer repertoire of tools for shaping the frequency response of the closed loop system.

Dynamic Behavior and Stability of Closed-Loop Control Systems

their daily work. The PID algorithm can be approached from many different directions. It can be viewed as a device that can be operated with a few empirical rules, but it can also be approached analytically. This chapter gives an introduction to PID control. The basic algorithm and various representations are presented in detail. A description ...

Chapter 11 Dynamic Behavior and Stability of Closed-Loop Control Systems - In this chapter we consider the dynamic behavior of processes that are operated using feedback control. - This combination of the process, the feedback controller, and the instrumentation is referred to as a feedback control loop or a closed-loop system.

PID Control - Caltech Computing

Consider a unity feedback system with the plant G p (s) and the controller G c (s). PID control action is applied to the plant. The PID controller has the transfer function. Use the values T I = 0.2 and T D = 0.5. a. Identify the open-loop poles and zeros. b. Identify the root locus parameter K in terms of K P.

11.2 The Feedforward Concept. Chapter 10 illustrated the concepts of feedforward control and showed that one problem it gives us is drifting of the PV from the systems SP value. This is caused solely because the PV is not taken into account in feedforward control, if it was it would become a feedback (closed loop) controlled system.
