Solid-state NMR (SSNMR) spectroscopy provides a nuclear site-specific probe of molecular structure, electronic structure, and overall crystal structure. In comparison with diffraction methods, w a significant extent from a degree of long-range ordering of molecules in solids, NMR methods tend to provide much more local information.

Crystallographers often explicitly state the type of beam used, as in the terms X-ray crystallography, neutron diffraction and electron diffraction. These three types of radiation interact with the different ways. X-rays interact with the spatial distribution of electrons in the sample.

After completing this session, you should be able to: Classify materials as n- or p-type, and explain how simple p-n junction devices work. Derive the 7 crystal systems by varying the lattice const and angles α , β , γ . For a given repeating pattern, determine the crystal basis and Bravais lattice.

Nuclear magnetic resonance crystallography (NMR crystallography) is a method which utilizes primarily NMR spectroscopy to determine the structure of solid materials on the atomic scale. Thus, NMR spectroscopy would be used primarily, possibly supplemented by quantum chemistry calculations (e.g. density functional theory), [1] powder diffraction [2] etc.
