Germination occurs in many seeds as soon as moist, warm conditions are available. These immediately stimulate enlargement in a system which had previously remained constant in size. The promotion of activity ultimately leads to the establishment of the normal, growing organism, but the change is a gradual one, and although the beginning of germination is well enough defined its termination is ...

But such seeds can be matured artificially by storing fruits or cones for a certain period of time to allow embryos to mature completely and to germinate. 31 Investigation of the germination physiology of seeds of several indigenous tree species of Ethiopia have shown that a certain level of maturity must be reached for the successful germination of the seeds to produce the required amount of ...

Physiological, Biochemical and Other Changes Accompanying Seed Germination. Physiology of Seed Germination: All the viable seeds which have overcome dormancy (if any) either naturally or artificially will readily germinate under suitable environmental conditions necessary for seed germination i.e., water, O 2, temperature and in some cases light.

Biology of seed development and germination physiology

Seed development is now covered in two chapters so that reserve synthesis and its regulation could be separated from the developmental aspects of embryogenesis and seed maturation. The final chapter on some agricultural and industrial aspects of seeds and germination includes new sections on viability and longevity, and somatic embryos and synthetic seeds.

Physiology of Seed Germination - Biology Discussion

Seeds are highly dehydrated and naturally require water before germination. The first phase of seed germination is water imbibition till critical level of water is attained. Once the imbibition is completed, seeds begin to germinate and seedling emerges out. Radicle or root penetrates the seed coat and is followed by shoot emergence.
