EVERYDAY HEAT TRANSFER PROBLEMS - GBV

By assuming constant thermophysical properties and no heat sources in the pipe wall, the heat conduction equation for the temperature distribution, T , is: $\frac{d^2 T}{dR^2} + \left(\frac{1}{R}\right) \frac{dT}{dR} = 0$ If the temperatures at the inner surface, T_i , and the outer surface, T_o , of the pipe wall are known, Eq.

Heat generated in pipes or in orifices due to fluid friction in high-viscosity fluids can be substantial. In the present analysis, the heat generated in steady-state and fully developed pipe flows is investigated for fluids of different viscosities.

Conduction heat transfer in printed circuit boards (PCBs) has been studied extensively in literature i.e., B. Guenin [4]. The layered structure of a printed circuit board is treated using two different thermal conductivities; one is in-plane thermal conductivity and the other is through-thickness thermal conductivity.

Everyday Heat Transfer Problems Sensitivities to Governing Variables

Heat is a type of energy transfer that is caused by a temperature difference, and it can change the temperature of an object. As we learned earlier in this chapter, heat transfer is the movement of energy from one place or material to another as a result of a difference in temperature. Heat transfer is fundamental to such everyday activities as home heating and cooking, as well as many industrial processes.

A hot drawn bar, assumed to be moving at a constant velocity out of a die at constant temperature, will be treated as a one-dimensional heat transfer problem. The Biot number for the bar, $h t D/2k$, will be assumed to be less than 0.1, to assure no radial variation of temperature in the bar.

Transient heat transfer which occurs during the cooling of a chip can generally be solved by using the same energy balance equation as in Chapter 11, without the radiation heat transfer effects. The temperature of a chip can be investigated by using unsteady-state and one-dimensional heat transfer rate equations in rectangular coordinates.

This problem can be approached by assuming one-dimensional steady-state heat transfer in rectangular coordinates and with constant thermophysical properties. Convection heat transfer per unit area, from hot gases to the hot side of a wall that separates the cold medium and the hot gases, can be written as:

The design of a heat exchanger can be a good challenge for engineers. The design methods cover a vast variety of engineering disciplines, such as heat transfer, fluid mechanics, stress analysis, corrosion, materials, economics, etc. There are two popular heat transfer design methods covered in literature; see References [5], [6], [10] and [15].

The pipe is filled with stationary water, and is only exposed to the environment where there is convection heat transfer between the outer surface of the insulation and the environment. The time that it takes the water in the pipe to start freezing is analyzed, and its sensitivities to governing independent variables are investigated.
