The Brayton cycle analysis is used to predict the thermodynamic performance of gas turbine engines. The EngineSim computer program which is available at this web site, uses the Brayton cycle to determine the thrust and fuel flow of an engine design for specified values of component performance.

Thermodynamic performance analysis of gas-turbine power-plant

In thermodynamic, the thermal efficiency is a dimensionless performance measure of a device that uses thermal energy, such as an internal combustion engine, a steam turbine or a steam engine, a boiler, furnace, or a refrigerator for example. For a heat engine, thermal efficiency is the fraction of the energy added by heat (primary energy) that is converted to net work output (secondary energy).

The pressure ratios for the maximum specific output and efficiency can vary greatly, depending on whether the gas turbine cycle features a recuperator, inter coolers or even intermediate heating. The turbine inlet temperature also pushes up the optimal pressure ratio. The pressure level of the cycle, on the other hand, has no effect.
