For an open channel flow to be uniform, the same conditions must apply to the channel. That is, it must be straight and have a constant cross section. This is not sufficient, however, because the water surface must also be parallel to the channel slope.

This has important implications for the control of any open channel flow, and in particular the estimation of water levels for a given volume discharge. If a flow is supercritical, a disturbance at the water surface is unable to travel upstream (relative to a stationary observer) because the velocity of the flow exceeds the wave velocity ($Fr > 1$).

The basic approximation in open channel hydraulics, which is usually a very good one, is that variation along the channel is gradual. One of the most important consequences of this is that the pressure in the water is given by the hydrostatic approximation, that it is proportional to the depth of water above.

Usually dispatched within 3 to 5 business days. Analysis of open-channel flow is essential for the planning, design, and operation of water-resource projects. The use of computers and the availability of efficient computational procedures has simplified such analysis and made it possible to handle increasingly complex systems.
