Internet Architecture. This protocol further determines how to transform a stream of bytes in an IP packet, while ensuring quality of transport this IP packet. Both protocols, assembled under the TCP / IP abbreviation, are in the form of a layered architecture. They correspond to the packet level and message-level reference model.*

Internet layer. The Internet Protocol is the principal component of the internet layer, and it defines two addressing systems to identify network hosts' computers, and to locate them on the network. The original address system of the ARPANET and its successor, the Internet, is Internet Protocol version 4 (IPv4).

Internet layer - Wikipedia

Internet architecture. A short form of the compound word "inter-networking". This architecture is based in the very specification of the standard TCP/IP protocol, designed to connect any two networks which may be very different in internal hardware, software, and technical design.

Layer 2: Internet layer. Selection of a packet switching network which is based on a connectionless internetwork layer is called a internet layer. It is the layer which holds the whole architecture together. It helps the packet to travel independently to the destination. Order in which packets are received is different from the way they are sent.

Internet Architecture And The Layers

The first corollary is the principle of layer separation: Internet regulation should not violate or compromise the separation between layers designed into the basic architecture of the Internet. The second corollary is the principle of minimizing layer crossing, i.e., minimize the distance between the layer at which the law aims to produce an affect and the layer directly affected by legal regulation.

The Layers of IoT

Network architecture is responsible for standards and frameworks for the various layers of communications networks, such as the seven open systems interconnection model, which includes: physical, data link, network, transport, session, presentation, and application layer.

The evolutionary kernels of the Internet architecture include IPv4 in the network layer, and TCP and the User Datagram Protocol (UDP) in the transport layer. These protocols provide a stable framework through which an always-expanding set of physical and data-link layer protocols, as well as new applications and services at the higher layers, can interoperate and grow.
