In a parallel circuit, each device is connected in a manner such that a single charge passing through the circuit will only pass through one of the resistors. This Lesson focuses on how this type of connection affects the relationship between resistance, current, and voltage drop values for individual resistors and the overall resistance, current, and voltage drop values for the entire circuit.

9.2.2 Parallel resistances and the junction rule. One of the simplest examples to analyze is the parallel resistance circuit, of which figure b was an example. In general we may have unequal resistances (R_1) and (R_2) , as in c/1. Since there are only two constant-voltage areas in the circuit, c/2, all three components have the same voltage difference across them.

In a parallel circuit, the current from the power source is split across the circuit. This results in different amounts of current flowing, depending on the resistances of each branch. Also, as you add branches to the circuit, the total current always increases; you need to check that your power supply is capable of handling the extra current, or the whole circuit will be starved of current.
