Positron-emission tomography (PET) is a nuclear medicine functional imaging technique that is used to observe metabolic processes in the body as an aid to the diagnosis of disease. The system emitted indirectly by a positron-emitting radioligand, most commonly fluorine-18, which is introduced into the body on a biologically active molecule called a radioactive tracer.

Principles and Practice of PET and PET/CT

The average positron range in matter depends on the positron's energy and material characteristics, such as the density and the atomic number. For 18F-FDG, positron ranges are rather short, typically 1 millimeter. At the end of its path, the positron, being anti-matter to electrons, will annihilate
