The high-speed stability problem of semi-displacement hulls may also occur with planing hulls. In one particular project, HSVA investigated alternatively a semi-displacement and a planing hull design for a 45-knot yacht. The planing hull had lower calm-water resistance for high speeds, but the semi-displacement hull performed better in waves.

Savitsky and Brown (1976) proposed empirical formulas for calm water resistance, added resistance and bow acceleration in waves and lifts acting on stern wedges of prismatic planing hulls. Gerritsma et al. (1993) carried out high-speed model tests for the prediction of resistance and stability of some planing crafts.

Planing hull drag prediction using the Savitsky method Planing is a hydrodynamic state where a hull is dynamically supported by pressures that are developed by the forward motion of the vessel. Before addressing the state of planing, let's consider what a boat needs to do before getting up on plane.

Blount and Fox (1976) made resistance prediction of existing planing hulls: non-mono-hedral and non-constant beam to define the "effective beam and deadrise" to use in the prismatic plate planing equations. The conclusion was that the maximum chine beam and the deadrise at mid-chine length i.e., equivalent deadrise angle resulted in best ...

assist you in choosing the right planing boat for your needs. How do Hydrodynamics relate to planing of a boat? A planing hull uses hydrodynamic lift to rise up and out of the water to reduce resistance. In order to plane the hull must achieve an appropriate angle of incidence to the water flow, trimming up by the bow to generate lift.
