Seedling dry weight and weight of mobilized seed reserve increased with seed germination, while seed reserve utilization efficiency decreased after the first rise. The early seedling growth is firstly determined by the mobilization of storage reserve followed by the conversion efficiency of utilized seed reserve into seedling tissues.

Germination of Seeds: Stages & Factors involved

Cool temperatures also allow the seed to digest some of its food reserve, giving it energy. For these seeds, putting them in the refrigerator for a specific period of time allows them to gain sufficient oxygen and energy to germinate (Colorado Seed Laboratory 2009). Steps of Seed Germination. Imbibition. The seed rapidly takes up water and the seed coat swells and softens.

Seed Physiology, Volume 2, Germination and Reserve Mobilization, addresses some of the major unanswered questions about seed dormancy, germination, and post-germination development of the seedling. The book contains seven chapters and begins with two studies on dormancy—one on the structural constraints to germination and another on metabolic barriers preventing germination.

Germination and Reserve Mobilization - 1st Edition

Seeds with intact opercula did not germinate, but demonstrated embryonic reserve mobilization and cell elongation, indicating that dormancy in *B. capitata* is related to the incapacity of the embryo to dislocate the operculum.

The endosperm contains abundant protein and lipid reserves, and the embryo has additional starch reserves. Germination occurred only in seeds with their opercula removed and involved the elongation of the cotyledon cells and meristematic activity in the "M zone" located between the embryonic axis and the proximal extremity of the embryo.

Seed Germination and Dormancy - Plant Cell

The uptake of water by seeds is called imbibition, which leads to the swelling and the breaking of the seed coat. When seeds are formed, most plants store a food reserve with the seed, such as starch, proteins, or oils. This food reserve provides nourishment to the growing embryo.

seed physiology - SlideShare

Besides the embryo, reserve food material necessary for seed germination is present. It mostly contains starch, fats and other reserve food material with least amount of moisture. Hence the seed appears very dry and can be stored for many years without any damage by infection etc.
