Antennas for portable devices may be small in terms of [2]:

- 1. electrical size. The antenna can be physically bounded by a sphere having a radius equal to freespace $\lambda/2$. Planar inverted-F antennas with shorting pins or/and slots are typical examples of this category.*
- 2. physical size. An antenna which is not electrically small may feature a substantial size*

The designer of portable tracking devices is trapped in a space with three types of boundaries. One boundary is the laws of physics that limit how effective a small antenna can be – there is not much that can be done about this except to make use of good engineering practice and experience.

Consequently, it is less important to maximize the efficiency of the antenna. Because portable devices are getting smaller and thinner, the space allowed for an embedded FM antenna is very limited. It is still important to maximize antenna size, but the energy collected by an embedded antenna is small.
