In vibrational spectroscopy, transitions are observed between different vibrational states. In a fundamental vibration, the molecule is excited from its ground state ( $v = 0$ ) to the first excited state ( $v = 1$ ). The symmetry of the ground-state wave function is the same as that of the molecule.

Multiplication of a non-singular matrix  $A$  (i.e.,  $\det A \neq 0$ ) by a non-singular matrix  $B$  gives a non-singular matrix  $C = AB$ , because  $\det C = \det A \det B \neq 0$ . The  $A_{1g}$  to  $B_{1u}$  and  $A_{1g}$  to  $B_{2u}$  transitions are symmetry forbidden and thus have a lower probability which is evident from the lowered intensity of their bands. The singlet  $A_{1g}$  to triplet  $B_{1u}$  transition is both symmetry forbidden and spin forbidden and therefore has the lowest intensity. This transition is forbidden by spin arguments ...

Raman scattering or the Raman effect / ? r ?? m ?n / is the inelastic scattering of photons by matter, meaning that there is an exchange of energy and a change in the light's direction. Typically this involves vibrational energy being gained by a molecule as incident photons from a visible laser are shifted to lower energy.
