**In the LCAO approach, molecular orbitals are constructed by selecting sums and differences of atomic orbitals. ***An orbital is just a bit of space where there is a 95% chance of finding that particular electron. If an electron is in a particular orbital, you know about its energy - but there is no way of knowing how it is moving around within that orbital. The big problem in all of this, to my mind, is the confusion in the words "orbit" and "orbital".***

***A molecular orbital is essentially the path which an electron takes around a molecule. This is very similar to an atomic orbital, except that a molecular orbital is a path which takes into account the field of more than one nucleus. There are two types of molecular orbital, a bonding one and an anti-bonding one.***
