*The tip of the fuselage nose of an airliner flying at Mach 0.85 will see air temperature to rise by 14.45%. If the air at altitude has a temperature of 220°K (-53.15°C), the air temperature at the stagnation point will be 251.8°K (-21.36°C). But past the stagnation point the air will accelerate and become faster than flight speed.*

*Thermal lift is often used by birds, such as raptors, vultures and storks. Although thermal lift was known to the Wright Brothers in 1901, it was not exploited by humans until 1921 by William Leusch at the Wasserkuppe in Germany. It was not until about 1930 that the use of thermals for soaring in gliders became commonplace.*

*Using the Rudder in Thermal Flying by Mark Drela*

*A thermal column (or thermal) is a column of rising air in the lower altitudes of Earth's atmosphere, a form of atmospheric updraft. Thermals are created by the uneven heating of Earth's surface from solar radiation, and are an example of convection, specifically atmospheric convection.*

*RC Thermal Soaring*

*Establish a straight slow glide, and note the L/D and sink rate. Apply 20 degrees (or about 50%) left rudder, and just enough right aileron to keep the wings level. Some elevator may also be required to maintain pitch trim. The glider will now fly at a 10-15 degree right sideslip.*

*How Thermals Work | Boldmethod*

*The weaker parts of the thermal will fizzle out sooner, so finding the stronger bubbles means you can climb higher and will likely stay with the thermal for longer. Think of climbing faster as an added bonus. Flying with other pilots is the easiest way to understand where those stronger cores are.*
